## ABSTRACT

This report is a sequel to Human Resources in the Ozarks Region...With Emphasis on the Poor, published in May 1970 as Agricultural Economic Report No. 182. Prepared by the Economic Research Service, U. S. Department of Agriculture (USDA), in cooperation with the Agricultural Experiment Stations at the Universities of Arkansas and Missouri, AER 182 examined the socio-economic conditions of rural people in the Ozarks region of Arkansas, Missouri, and Oklahoma. In the sample of 1,413 household heads in that study, 31 percent or 439 heads, reported total or partial disabilities. The current report describes and analyzes these 439 heads and their households. Of these households, 41 percent were in poverty. Household heads' incomes were small because many were unable to hold regular jobs and most heads were of advanced age. They generally had low skills and very few had completed high school. Nearly 44 percent of those who had jobs were farmers. Medical expenses in households with disabled heads were quite high and only 70 percent of them had any health insurance. Keywords: Disability, poverty, income, education, employment, Ozarks region, rural areas.

## ACKNOWLEDGMENTS

The author expresses appreciation to Max F. Jordan and John L. McCoy, Human Resources Branch, Economic Development Division (EDD), Economic Research Service, USDA, for their assistance in planning the study. He is also grateful for the assistance of Bernal L. Green, EDD Field Staff, Fayetteville, Ark., for making the data from the original study available in a usable form.

## HIGHLIGHTS

Over 30 percent of household heads in a 1966 survey of rural Ozarks households were partially or totally disabled. Perhaps 10 to 15 percent of these 439 heads have the potential for rehabilitation and subsequent gainful employment.

Nearly a fourth of the household heads reported disabilities they considered to be permanent, and nearly a fourth indicated they were totally disabled. Over 83 percent of the male household heads and 90 percent of the female household heads had visited a doctor or clinic for help during the past year (1965). Medical expenses were high; in 1965, four out of 10 had medical or dental bills from \$100 to \$500. Seventy percent of the disabled household heads had insurance for these bills; the rest relied on help from public agencies, friends, and relatives.

Only one in six operated a farm; 86 percent of these operators owned the land they farmed. In both farm and nonfarm households, some food was purchased for home consumption. Two-person households were reported by 54 percent of the farm and 44 percent of the nonfarm households. At the other end of the scale, 18 percent of the farm and 15 percent of the nonfarm households had five or more members.

More than half the disabled household heads were over 65 years old. Most heads were male. Generally, more households headed by females were in poverty (based on household size and income) than were those headed by males. Less than 3 percent of the households with female heads but 15 percent of those with male heads had incomes of \$5,000 or more a year.

Incomes were small--annual earnings for seven out of 10 households were less than \$2,000. Occupation of the disabled household head was another influence on the size of income; household heads in unskilled jobs earned less than \$3,000 annually. Only operators or professional workers earned \$5,000 or more a year.

Few disabled household heads held more than one job--18 percent of those living on farms and less than 1 percent of those not living on farms. Absenteeism due to disability was not high. Less than 30 percent of disabled household heads working full-time lost up to half a year from their jobs. On the average, part-time workers missed more weeks than full-time workers did.

Nearly 60 percent of the disabled household heads reported holding one job during a 5-year period preceding the 1966 survey. Household heads 45 to 64 years old seemed to remain unemployed longer than did household heads in the other age groups.

Few disabled household heads had completed high school--one in nine--and only six held a college degree. Amount of education affected their economic status; heads with no formal education were in poverty or the marginal class (annual income of \$3,000-\$4,999), while none of the college graduates were in poverty. Over 80 percent of disabled household heads with a grade school education or less were in poverty.

The economic position of the disabled household heads seemed to influence the amount of education they thought their children needed. Household heads with household income of less than \$3,000 a year considered high school sufficient; household heads with household income of \$3,000 or more a year thought a college education was necessary.

A PROFILE OF DISABLED HOUSEHOLD HEADS AND SPOUSES IN  
RURAL AREAS OF THE OZARKS REGION

By O. Wendell Holmes<sup>1/</sup>

INTRODUCTION

Physical disabilities tend to decrease a person's earning potential. People who are totally disabled, especially if they have such poverty-linked characteristics as advanced age, low educational level, unemployment, lack of marketable skills, and little or no source of income, will almost certainly be in poverty. Similarly, those who are partially disabled and also have poverty-linked characteristics will probably be in poverty.

In a study of the socioeconomic condition of rural people in the Ozarks region in 1966, over 30 percent of the random sample of 1,413 household heads reported some degree of disability.<sup>2/</sup> Because it was thought that a profile of the disabled heads and their households would be useful in formulating and evaluating rehabilitative programs for them, the data for these households were analyzed in this report. The rural parts of the 125 counties delineated as the Ozarks Economic Development Region in 1966 constituted the study area.<sup>3/</sup>

LEVEL OF DISABILITY

Questions on various aspects of the health of the 1,413 respondents were asked in two different parts of the schedule used in the 1966 survey. All answers were based on the respondents' self-evaluation of their health. As mentioned, nearly a third of the household heads reported disabilities of some type (table 1).<sup>4/</sup> In an early part of the interview, household heads were asked their employment status; 88 indicated they were totally disabled and not working. Fourteen household heads who, at the beginning of the questionnaire, simply said they were retired changed their self-evaluation to being disabled and thus retired, after more thorough querying. In a later section that explored their health status more fully, 102 indicated they were totally disabled. This figure is the one used here and in the report by Hoover and Green as the number of household heads who were totally disabled.

<sup>2/</sup> Herbert Hoover and Bernal L. Green. Human Resources in the Ozarks Region...With Emphasis on the Poor, Econ. Res. Serv., U. S. Dept. Agr., cooperating with Agr. Expt. Stations, Univ. Ark. and Univ. Mo., Agr. Econ. Rpt. 182, May 1970.

<sup>3/</sup> The sampling procedure is explained in the reference cited in footnote 2.

<sup>4/</sup> Tables appear at the end of this report.

Nearly all (97 percent) of the disabled household heads said their disability limited their ability to work or do chores (table 2). Spouses were not as disabled; less than half had disabilities that limited their ability to work. Of the 151 disabled spouses, only 14 were totally disabled.

### Permanency of Disabilities

The respondents were also asked which of their disabilities were more or less permanent. As was required from the makeup of the sample, all of them reported having a disability of some type, with varying degrees of permanency. Nearly one-fourth of the respondents considered themselves to be totally disabled and the remainder, partially disabled. A disability due to problems involving the heart or brain was the most frequently mentioned specific handicap by both the totally and the partially disabled household heads. Nearly one in six household heads reported such a handicap, which was a considerably higher proportion than that for arthritis, the next most frequently mentioned specific handicap. As shown in table 3, household heads mentioned a large variety of disabilities, with various frequencies. For the spouses, the general pattern was the same, with some types of disabilities mentioned frequently and a few mentioned only occasionally (table 4). As with the household heads, the most commonly mentioned specific infirmity of spouses with total disability involved the heart or brain. For those with partial disability, arthritis, abnormal blood pressure, and problems involving the heart or brain were most often mentioned and in that order. Accidents resulting in disabilities were also frequently mentioned by the household heads. None of the disabled spouses indicated any total disability due to accidents.

The differential in number of spouses and household heads totally disabled from accidents may be because household heads had work-related injuries and their evaluation of their disability may have been in reference to a full-time job away from home. Spouses, however, may have evaluated their accident-related injuries with regard to the ability to carry out housework.

### Medical Help Sought

As would be expected, a large proportion of the disabled household heads had visited a doctor or clinic within the past year. Over 83 percent of the male and 90 percent of the female household heads had made such a visit. The frequency with which the spouse had visited a doctor was about the same as for the head (table 5). Many of their disabilities were evidently not serious enough to warrant annual visits. Most of the disabled household heads who did seek medical help went to their own private physician. A few visited a clinic or a chiropractor, or used home remedies (table 6).

Many reasons were given for visits occurring within the past year (1965). However, the reason most often mentioned by both partially and totally disabled household heads and spouses was that of seeking help for problems involving the heart or brain (tables 7 and 8). Accidents necessitating medical help were another common cause for visits to the doctor.

## Medical Insurance

In 1965, four out of 10 of the partially or totally disabled household heads reported family medical or dental bills of \$100 to \$500. As would be expected, families with household heads who were totally disabled had more often incurred greater expenses. A higher proportion of respondents with partial disability reported bills that placed them in the lower dollar categories--in particular, those under \$100--shown in table 9.

About two-thirds of the disabled household heads reported having some health insurance. The proportion was higher for the partially disabled (71.5 percent) than for the totally disabled (58.8 percent). The type of health insurance most frequently reported by both partially and totally disabled household heads was Medicare. Some had commercial insurance and some had a combination of Medicare and commercial insurance (table 11).

Since possession of health insurance was reported by only about 70 percent of the household heads, many were without any protection against medical expenses (table 12). Ten percent of the disabled--nearly the same number of partially and totally disabled--had medical expenses of \$50 or more and no health insurance. They used various methods to pay these bills. The most commonly reported method was that of obtaining help from a welfare organization. Assistance was also received from relatives, veterans' services, and other public agencies (table 13).

## DELINEATION OF POVERTY

Though household income alone has frequently been used to determine whether a family is in poverty, such a measure has shortcomings. To provide a better measuring tool, the Economic Research Service developed a household size-income classification. In this, size of household is used to adjust income data and bring both measurements--household and income--to a more common and comparable base. The first two classes contain those households in poverty. Class 3 has the marginal group; the household is in or out of poverty depending on several factors. Classes 4 and 5 contain those households not in poverty (table 14).<sup>5/</sup>

With this classification method, over 41 percent of the disabled household heads were considered to be in poverty. Of these, nearly 8 percent were in serious poverty, with annual household incomes less than \$1,000 and family size ranging from one to eight persons. About one-third of the household heads were in class 3, the marginal category. With a small change in income or the addition of another family member, these households could easily move into class 2 and be considered in poverty. Their marginal situation makes their economic position hardly tenable.

Compared with the entire sample in the Ozarks study, the disabled respondents were in a poorer economic position. Only 25 percent of all respondents in the sample were in poverty, compared with over 41 percent of the disabled respondents. The marginal class contained 33 percent of the disabled household

---

<sup>5/</sup> For more detail on development of these classes, see the Hoover and Green report cited in footnote 2.

heads, compared with 28 percent of all household heads in the sample. Hence, more of those in the total sample were out of poverty and in classes 4 and 5. Disability, when coupled with large family size and small income, is a real hardship for many households.

## GENERAL CHARACTERISTICS OF HOUSEHOLDS

### Residence and Family Size

The majority of the disabled household heads studied lived in residences that were not directly related to farming. Only one in six lived on a farm. The most frequently reported size of household for both farm and nonfarm residents was two persons (table 15). Fifty-four percent of the farm and 44 percent of the nonfarm households were composed of two persons. Single-member households were reported by 25 percent of the nonfarm residents, but by only 3 percent of the farm residents. The second most common household size for farm residents was three persons, which was nearly identical to the mean household size of 2.99. The mean size of nonfarm households was slightly smaller at 2.62. Large households of five or more members were found among 18 percent of the farm and 15 percent of the nonfarm households with disabled household heads.

Family size--the number of persons in the household--relative to the amount of household income is frequently used as an indicator of economic well-being. About half the households with two members had annual incomes between \$1,000 and \$1,999 (table 16). One in eight households had incomes under \$1,000, and four out of 10 of these contained more than one person. For those households with less than \$1,000 annual income, having more than one member put them in serious poverty.

The most commonly reported size of household over all income levels was two persons. This was also true for each income level individually, except the lowest. For households at that level, nearly six out of 10 had one member.

### Farm Tenure

Landownership was the most common method of controlling land among the 72 disabled household heads who operated farms. Eighty-six percent of these farmers owned all the land they operated and an additional 6 percent operated both owned and rented land (table 17). The remaining operators rented their land, except one who functioned as a manager.

### Home Production of Food

Most of the farm households with disabled heads produced some food for home consumption. Though the amount was not reported for individual households, eight of nine farmers produced garden products, poultry, pork, or beef (table 18). Over 60 percent of the nonfarm residents produced some food for home use, primarily garden products, though a few raised some meat animals. Poultry was the second most frequently mentioned item, followed by beef and hogs, for both farm and nonfarm households.

## GENERAL CHARACTERISTICS OF HOUSEHOLD HEADS

### Age

The mean age of all household heads in the 1966 Ozarks study was 55. Disabled heads were considerably older, with a mean age of 64. The median age for disabled household heads was 66. More than half the disabled household heads were over 65 and nearly seven out of 10 were over 55. Only 4 percent were under 35.

The mean age of the disabled farm residents was nearly 4 years less than that of the disabled nonfarm residents (table 19). Up to a certain point, advanced age and disability seemed to go together. The percentage of disabled nonfarm household heads increased steadily until the 75-year category was reached, when the percentage declined. The situation was similar for farm residents, except that the percentage increased through age 64 and then dropped off. At the younger age levels, most of the disabilities seemed to be partial. At age 35 and up through age 65, most of the respondents indicated that their disabilities were total. From age 65 and up, a higher percentage of partial disabilities was reported (table 20).

Advanced age and low income seem to be positively related among the disabled household heads in the Ozarks. In all five of the household size-income classes, more than two-thirds of the respondents were 55 or over (table 21). In the two poverty classes and the marginal class 3, over three-fourths of the respondents were 55 or over. These proportions are considerably higher than for the entire Ozarks sample, where the percentage over 55 years ranged from 37 for household heads in class 4 up to 70 for household heads in class 2.

### Sex

In general, disabled male household heads outnumbered disabled female household heads by more than three to one (table 22). The second household size-income class (poverty class 2) had the largest proportion of male household heads of any class, and the third household size-income class (the marginal class) had the largest proportion of female household heads. Generally, however, households headed by males had less tendency to be in poverty than households headed by females.

The sex of the disabled household head was a very important factor in income-producing ability. Only one in 13 male household heads but one in four female household heads had household incomes which put them in the lowest income category--less than \$1,000 (table 23). The situation was similar for the next lowest category--\$1,000-\$1,999--which contained less than one in three of the households headed by males but one in two of those headed by females. The other five income categories--\$2,000 up to \$10,000--each had a considerably greater percentage of male household heads than female household heads. Less than 3 percent of the households with female heads had incomes of \$5,000 or more, compared with nearly 15 percent of the households with male heads.

## EMPLOYMENT AND INCOME

Household heads were in four employment status groups: employed, either full or part time; retired; totally disabled; and housewives and a few household heads who were in the labor force but unemployed (table 24). The first three groups each contained nearly 30 percent of the disabled household heads.

Nearly 70 percent of the household heads reported annual household income of less than \$3,000 and 46 percent had annual household income of less than \$2,000 (table 25). Of those household heads who were employed full-time, 40 percent reported household income of less than \$3,000 a year. Over 62 percent of the household heads employed part-time had annual household income of less than \$3,000. Most of the other disabled household heads--unemployed, housewives, retired, and totally disabled--had household income below \$3,000 a year.

### Occupation of Household Head

Size of income received by disabled heads of households varied depending on their occupation. Most household heads in unskilled occupations--such as farmer, service worker, laborer, and clerical worker--reported annual income under \$3,000 (table 25). Among household heads in all but five occupations (professional worker, managerial worker, craftsman, operator, and nonfarm laborer), more than half reported income less than \$3,000 annually. In only two occupations (professional worker and operator) did over half the disabled household heads have an income of \$5,000 or more annually.

### Multiple Employment

Multiple employment of disabled household heads living on farms generally involved one off-farm job in addition to that on the farm. Very few disabled household heads held more than one job (table 26). Multiple employment was reported by only 18 percent of the farm household heads and less than 1 percent of the nonfarm household heads.

For the seven farmers with multiple employment, the other job or jobs generally involved a skill or trade. Clerical work, labor, and craftsman were the jobs most commonly reported (table 27).

### Regularity of Employment

Although all household heads studied here were by their own admission disabled, absenteeism from work because of disability was not great. Most workers, either heads or spouses who were also disabled, reported losing only 1 to 4 weeks from work the previous year because of disability. Less than 30 percent of the household heads were absent as much as half a year from their jobs (table 28).

For the disabled household heads working part-time, absenteeism was fairly evenly divided between those who were absent 12 weeks or less and those who

were absent 25 or more weeks a year. Since the part-time workers may have greater health problems than full-time workers, their absenteeism rate may be higher. The number of disabled spouses working part-time was so small that no generalization can be made concerning the amount of time they lost from work due to disability.

### Unemployment

Nearly all disabled household heads indicated they had been in the labor force at some time in the 5 years preceding the study. The highest percentages of those who had been unemployed at some point during the 5 years were household heads under 35 and household heads 45 to 54 years old. Most household heads without jobs had been unemployed only once in the 5 years (table 29). One had been unemployed three times; another, six times. The length of time the household head was unemployed varied considerably. For one man in the category of 45-54 years, unemployment had been a real problem. He had experienced at least six periods of unemployment in the 5-year period. For the others, as age increased, length of unemployment generally increased. Household heads 45 to 64 years old seemed to experience longer periods of unemployment; during the 5 years considered, nine of the 20 in this category had periods of unemployment that lasted 5 months or more (table 29).

Job tenure was well established for the nearly six out of 10 disabled household heads who reported having held one job during the 5-year period (table 30). As age increased, a greater percentage of these respondents reported having had one job. With increasing age, the likelihood of obtaining another job diminishes. Older people may realize this and be more apt to try to retain their current jobs than would younger people. A few household heads reported having had four or more jobs in the 5 years preceding the study.

Most of the disabled household heads did not consider themselves to be in the labor force. The disabled, housewives, military personnel, students, and the retired are generally excluded. Of the 102 household heads who reported total disability, only six were in the labor force (table 31). Of the partially disabled household heads, 30.3 percent were in the labor force.

Of the six in the labor force who were totally disabled, four were farmers or farm managers, one was an operator, and one was in the manager, official, and proprietor category. Partially disabled household heads in the labor force were employed in a number of occupations. The occupation most frequently given was that of farming, as was true for the totally disabled. Other occupations--such as operative, craftsman, laborer, manager, service worker, clerical worker, and professional worker--were also mentioned.

### Effect of Disability on Earning Ability

Disability, either total or partial, had a marked impact on the earning ability of the household heads (table 32). About two-thirds of the disabled household heads had annual incomes of less than \$3,000. Only 12 percent of the

partially disabled and 12 percent of the totally disabled household heads had annual household incomes over \$5,000 during 1966. Half the household heads reporting disabilities which they regarded as total were in poverty classes 1 and 2 (table 33). Only 20 percent of those with total disability were in classes 4 and 5 and thus not in poverty. The situation was similar for those with partial disability, with 38 percent in poverty and 26 percent in classes 4 and 5.

### Sources of Income

Sources of income differed considerably in the number of times they were mentioned. For those household heads who lived on a farm, income from farming was reported the most frequently, as would be expected. In fact, it was reported twice as often as the next source, income from retirement funds (table 34). Four out of 10 of the farm residents reported having farm income. Dependence on transfer funds, such as unemployment compensation and welfare, was reported by only one in eight. Income from retirement funds was the most frequently mentioned single source for the nonfarm resident. Welfare and unemployment income were reported by 37 percent of all nonfarm respondents. As would be expected, income from farming was mentioned only rarely among the nonfarm residents. For both groups, income from salaries was the third most often mentioned source.

Nearly three-fourths of all farm households with disabled household heads reported gross farm income of less than \$2,500 (table 35). This large percentage is indicative of the poverty existing among many of the disabled farm operators in the Ozarks. Regardless of family size, a gross income of this amount would put its recipient in poverty. Also, at the higher income levels--for example, \$7,500 gross sales and up--many units would be in poverty if the family contained as many as three members.

### Number of Earners in Household

The incidence of income earners was heaviest in favor of one for the nonfarm households and two for the farm households (table 36). More than 50 percent of the nonfarm households had one earner, compared with 44 percent for the farm households. A few nonfarm households had five or more income earners and a few farm households reported no earners.

## EDUCATION

### Attainment by Household Head

Educational achievement varied among disabled household heads. Although nearly three out of four had completed eight grades or less, more of the household heads had received no schooling than had attended college. Only one in nine had completed high school, and only one in 31 had any college education (table 37).

The number of years of education seemed to affect which household size-income class a disabled household head would be in. Disabled household heads with no formal education were either in poverty (class 1 or 2) or in the marginal category (class 3) (table 38). On the other hand, none of the college graduates were in poverty. For those with just a grade school education, the odds of being in poverty seemed great. More than 80 percent of the respondents with 1 to 8 years of education were either in poverty or the marginal category. As the number of years of education increased, the percentages in classes 1, 2, and 3 were reduced.

The impact of education on the number of disabled household heads in a particular poverty class was especially marked when the number of persons in classes 1 and 2 who had a high school education was compared with the number in classes 1 and 2 who had less than a high school education. None of the disabled household heads in class 1 and only 4 percent in class 2 had a high school education. The number of persons with a high school education did increase with each higher household size-income class. The rate of increase was very small for the first few classes but rose substantially for classes 4 and 5. Only 8 percent in class 3 but 24 percent in class 4 and 32 percent in class 5 had a high school education. Eighty-eight percent of all the disabled household heads had less than a high school education.

Nearly 50 percent of all disabled household heads with 8 years or less of education were in poverty, compared with only 21 percent of those with 9 or more years. A few of those with less than 8 years of education were able to get enough income to keep out of poverty and above the marginal class. On the other hand, some with a high school education were not able to stay out of poverty.

The amount of education which the disabled household heads had received decreased in the older age groups. Table 37 shows the number in each age group by the years of education they had received. As the age level increased, a smaller proportion had completed 9 or more years of schooling. Generally increasing interest in getting an education was evident among the younger age groups. Of those below age 35, 44 percent had completed high school, compared with only 14 percent of those aged 35-54. However, very few of the household heads, regardless of age level, had any college (3.2 percent), and fewer (1.4 percent) had completed college.

A considerable difference existed in the employment status of disabled household heads relative to the amount of schooling they had. With one exception, all household heads who reported no education were either retired, unable to work, or housewives. The one exception was employed full time. Of the six household heads who were college graduates, four were employed full time, one was retired, and one was unable to work. The more education a household head had, the greater his or her chances of being employed. The probability of employment for a household head with an eighth-grade education was double that of one with less than 8 years of schooling. In addition, household heads with a high school diploma had a better chance of being employed than did household heads with some high school. Similarly, household heads with a college degree were more likely to be employed than were household heads with some college. Few of either the high school graduates or persons who had

attended college were employed part-time. Part-time work was common among those with less than a high school education.

Just as education was important in determining a disabled household head's employment status, it was also important in influencing his or her specific occupation. Some occupations seemed to be restricted to persons with certain levels of education (table 39). For example, all farm laborers were in the group with no more than a grade school education. None of the farmers, clerical workers, craftsmen, operators, housewives, unemployed, or household heads who were both retired and disabled<sup>6/</sup> had more than a high school education. However, no particular occupation was limited to those with high school training. The few household heads classified as professionals all had at least a high school education.

The other occupations--such as laborer, service worker, and manager--were not clustered at any one educational level. Laborers were found at all levels except among college graduates. Service workers had 5 to 16 years of schooling. The amount of education which managers had ranged from 1 year up through college. Members of the retired and disabled group could be found at all educational levels.

Generally, workers in certain occupational groups have greatly increased chances of being in poverty--for example, farm laborers as opposed to skilled workers, craftsmen, or professional workers. In the Ozarks, the chances of being in poverty were two out of three for disabled farm laborers and better than one out of two for those who were either unable to work or were in the retired and disabled groups. For household heads in the rest of the occupations, chances of being in either of the poverty classes varied from nearly one out of two for farmers to about one out of seven for operatives. No professional or clerical workers were in the poverty classes (table 40).

Less than 14 percent of all disabled household heads indicated that they were in nonfarm employment or that their last job had been in nonfarm work. Of these, nearly 40 percent indicated that they had averaged over 41 hours of work a week, with 8 percent reporting more than 60 hours a week (table 41). Nearly two-thirds worked 40 hours or less a week, and 13 percent worked 20 hours or less a week.

### Education of Children

The amount of education which the disabled household heads thought their children needed seemed to be tempered by their economic position. Generally, those with lower incomes thought their children needed fewer years of schooling than did those with higher incomes.

Compared with household heads having annual household incomes of \$3,000 or more, nearly twice as many household heads with annual household incomes under \$3,000 believed their children needed only a high school education

---

<sup>6/</sup> It could not be determined whether persons in the retired and disabled group retired early because of disability, retired at the usual age, or were affected by other circumstances.

(table 42). Similarly, 34 percent of those with annual household incomes under \$3,000 and 67 percent with annual household incomes of \$3,000 or more said their children needed a college education.

What household heads thought their children needed in the way of an education and what they expected their oldest son to obtain were not always the same. When queried concerning the amount of education expected of the oldest son, almost half of those in the higher income group expected their son to get a college education (table 43). In some cases, expectations for their son's education seemed greater than either their ability to finance it or the son's willingness or ability to get it. For the lower income group, about one-third expected their oldest son to complete college. The expectation of these parents for the education of their oldest son was about equal to their statement of his educational needs. It is not known whether heads with household incomes under \$3,000 annually were better able to provide for the education they expected of their children or whether these household heads reduced their expectations to conform more to their available resources.

Nearly half (48.7 percent) of the disabled household heads had children who had dropped out of school. The dropout rate was highest for children of families whose incomes put them in poverty. Over four-fifths of all dropouts were members of households with incomes of less than \$3,000 a year. Nearly three-fifths were in households with incomes of less than \$2,000 a year. Only 4 percent were in households with annual incomes of \$5,000 or more.

Reasons for dropping out varied by income. In households with annual incomes of less than \$3,000, 25.4 percent of the youngest of the children who dropped out of school left to get married (table 44).<sup>7/</sup> Nearly 20 percent wanted to go to work; the same percentage refused to go to school; and 14 percent were needed at home. In households with annual incomes of \$3,000 or more, the children dropping out of school most frequently left to go to work. Others left to get married, refused to attend, or had other reasons. Household heads in either income group rarely listed poor grades as the reason their children had quit school.

Most of the dropouts had completed grade school (table 45). One-fifth quit before entering high school and two-fifths quit after about 2 years of high school. One-fourth ended their formal education after completing high school.

#### IMPLICATIONS

A high incidence of disability in an area indicates insufficient or inaccessible medical and rehabilitative services--probably extending over a long period of time. In the Ozarks, the scarcity of these services is exacerbated by income deprivation, advanced age of the rural household heads, and geographic isolation--factors which affect accessibility to any services

---

<sup>7/</sup> Household heads who had any children at home or living away who did not finish high school were asked why the youngest of such children had quit school.

available. What, then, are the prospects for rehabilitating or otherwise helping members of this disabled group to live more comfortably?

The success of rehabilitation services depends on identifying people whose handicaps are such that these services may reasonably be expected to enable them to work. And their occupation would need to be consistent with any restrictions on their capacities and abilities.

Because the data in this report reflect household heads' diagnoses of disabilities, and medical confirmation was not obtained, estimating the rehabilitative potential of this group is hazardous. However, if it is assumed that one-third of those who are totally disabled and under age 55 and one-half of those who are partially disabled and under age 55 have the potential for rehabilitation, approximately 10 to 15 percent of all Ozarks household heads reporting partial or total disability may have rehabilitative potential.8/

Many of the remaining 85 to 90 percent of the disabled household heads need supplements to earned and other income. Four out of 10 of those aged 55 or older were in poverty. Disability payments and other nonwork income received by this group should be examined for adequacy.

---

8/ Upper age limits for rehabilitation are State-determined and may vary. However, because each person accepted for rehabilitation must have reasonable expectation of obtaining gainful employment, age 55 was used as the cutoff in the estimates. No age discrimination was intended.
